Exercise 1.3.1

Task 1

Answer the following using Python:

What is your name? Assign the value to the variable `name`

How old are you? Assign the value to the variable `age`

Are you a male or female? Assign the value to the variable `gender`

What state did you come from? Assign the value to the variable `state`

What language can you speak? Assign the value to the variable `language`

True or False, do you smile today? Assign the value to the variable `smile`

The list of the variables to create and assign values to are:

`name`

`age`

`gender`

`state`

`language`

`smile`

```
### CG T1
### write your code here:

name = "Adebayo Elisha"

age = 23

gender = "male"

state = "Ogun"

language = "English"

smile = True
```

Task 2

Explain why some variable names in the example are acceptable and why some are not in Python

	Sample of acceptable variable names	Unacceptable variable names
1	grade_test	test(grade)
2	covid_19_cases	covid-19-cases
3	term2	2 term
4	Sale_price_2021	2021sales_price

```
### CG T2
### Write your answer here for sample variable names

Python has rules and regulations to follow when naming variables of which some of
the rules are violated in the unacceptable variable names examples.

test(grade): variable names must not have special characters in them, can only con
tain letters, numbers and underscore, the parentheses () is the special characters
 here

covid-19-cases: a variable name cannot contain hyphen - it's a special character

2 term: a variable cannot start with an integer, also cannot have blank spaces in
between, we use underscore if we need to space characters.

2021sales_price: same reason as example 3, a variable cannot start with an integer

miva&learners: no special characters is allowed in variable naming, & is a special
 character.
```
